

Week 6 App Development Document

Project / Team

Project name: **Angels Archive**

Student name(s): **Angel Bautista**

Team strategy: **Individual project**

If you are working with a team, list every team member and explain who is responsible for each part. If you are working alone, write "Individual project."

0. Genre

Choose one genre and name it clearly.

Genre: **Movie**

Choose from Anime, Music, Movie, Horror, or another genre you identify.

Explain why this genre fits your app idea: **This genre fits my app idea because it is the most realistic and true-to-life idea that serves a purpose.**

1. Backstory

This app is based in the real world and comes from a personal problem I have dealt with for a while. I have been collecting movies, and whenever there are sales, I always forget which movies I already own and which ones I still need to buy. Before the app existed, I mostly tried to remember everything myself, but that became confusing as my collection started to grow.

In this world, I am the person who uses and needs the app. Since I enjoy buying and collecting films, I need a better way to keep track of my movies. The main problem is not having an organized place to see what films I already own and what films are still on my wishlist. This app matters because it would help me avoid buying duplicates, remember what I want to get next, and keep my movie collection organized in a way that is also visually pleasing.

2. Story / User Need

The user is Angel, and he likes collecting movies.

He needs an app to organize the movies he has and the movies he wants.

The problem is that he sometimes forgets which movies are already in his collection.

This matters because the app will help him stay organized and have a visual on what movies he already owns.

3. Product Definition

What are you building inside the story? **I am building a perfect visual representation of Angel's collection to help him keep track of his films**

What will the app help the user do? **Do not buy duplicates, and remember his wishlist/future watches**

What is the smallest useful version of this app? **Organization**

4. Variables

List containers of information your app may need.

Variable Name	Data Type	What It Stores	Example Value
Movie	String	The Name of The Film	Paris, Texas
Director	String	The Name of The Director	Wim Wenders
Release Year	Integer	The Year of Release	1984

5. Functions and Procedures

List actions the app needs to perform.

Function / Procedure	Purpose	Input	Output
AddMovie()	Adds a movie to the archive	Movie Name, Year, Director	Archived!
SearchMovie()	Searches the archive for the movie	Name, Year, Director	Matching Movies Shown
DisplayMovieInfo()	Shows notes/ Details of the selected Movie	Selected Movie	Notes:
Add to wishlist()	Adds a movie the user wants to Watch/Buy	Movie Name, Year, Director	Film added to Wishlist

6. Questions and Answers

Identify possible problems before coding.

Question: **What happens if I search for a movie and nothing shows up?**

Answer or plan: **The app will display a message saying “Movie not found”**

Question: **How will I know if a movie is owned or on my wishlist?**

Answer or plan: **The app should have a way to label the movie as either owned or wishlist so it is easy to tell the difference**

Question: **What if two movies have the same name?**

Answer or plan: **The app should also show the year and director so the user can tell them apart**

7. Execution Strategy

What will you build first?

I will build the main movie archive first. This will let me manually add movies I own with the movie name, release year, and director.

How will you test it?

I will test it by adding a few movies into the archive and then searching for them by name, year, and director. I will also test the wishlist option to make sure movies can be added there too.

What screenshots will prove it works?

Screenshots of a movie being added, the archive showing saved movies, a search result by name, a search result by year or director, and a movie added to the wishlist will prove it works.

What will you refactor or clean up if you have time?

If I have time, I will clean up the design, make the buttons and labels easier to understand, and organize the code so the archive and wishlist are easier to manage. I want the UI to look exactly the way I envision it in my head. A huge inspiration is the scroll mode the old iPods had that showed the album cover art,

8. Git Repository

Week 8 Application Change Log

App Name

Angel's Movie Archive

Previous Version

My previous Folder Maker App could:

- **Create a folder on the Desktop called AngelsMovieArchive**
- **Create text files for owned movies and wishlist movies**
- **Let the user add, search, and view saved movies**

New Version

This version adds: - **JSON saving: Movie information can be saved in a JSON file instead of only plain text files.**

- NuGet/package use: **I used a NuGet package to help work with JSON data.**

-File save location: **The app saves files inside the AngelsMovieArchive folder on the Desktop.**

- Three TODO items completed: **I improved saving, added better organization, and added more comments explaining functions and procedures.**

TODO Items I Chose

1. TODO item: **Add the JSON package to the resources**

- What I changed: **I added the JSON package so the app can save project information in JSON format.**

- Why it improves the app: **It makes the saved information more organized than just using a normal text file.**

2. TODO item: **Create a Project Class and JSON file**

- What I changed: **I created a ProjectInfo class to store the project name, folder location, created date, and folder count. I also made the app create a ProjectInfo.json file.**

- Why it improves the app: **This helps the app save important project details in one structured file.**

3. TODO item: **Refactor WriteFile procedure to take a string for data input**

- What I changed: **I changed the WriteFile procedure so it can write different text instead of always writing the same README message**

- Why it improves the app: **This makes the procedure more useful because I can reuse it for different files and messages.**

Functions And Procedures I Commented

- Name: **SaveMovieToJson**

- Purpose: **Saves movie information into a JSON file**

- Inputs: **Movie name, release year, director, and status**

- Output or result: **Creates or updates MovieArchive.json with the saved movie data**

Testing Notes

- What worked: **The app created the AngelsMovieArchive folder, created OwnedMovies.txt, WishlistMovies.txt, and MovieArchive.json, and saved movie information correctly.**

- What failed: **At first, I tried doing the tutorial inside my movie code, and it messed up everything, and I was so frustrated because I couldn't figure out how to make it work. I turned both into two different projects. So for my actual movie project, I added the JSON**

package, created the MovieInfo class, added SaveMovieToJson, and called it inside AddMovie so every movie saves to the JSON file too

- What I would improve in version 2.1: I would add an option to edit or delete movies, improve the search, and eventually make the app more visual with a cleaner interface.
